If you don't see the image in 5 seconds, please refresh the page, then try again!!!This invention relates to a tubular structure, and more particularly to a tubular structure for use as a heat exchanger, and is particularly suitable for the heat exchanger of the type in which the refrigerant is passed through a plurality of tubes, and which is particularly suited for use in a heat pump of the type in which a heat transfer fluid is caused to flow through the tubes to improve the heat transfer between the fluid and the refrigerant. The use of heat exchangers in the context of heat pumps is well known and a particularly advantageous form of heat exchanger is a so-called multi-pass heat exchanger in which the heat transfer fluid is caused to flow through a plurality of tubes and to be then directed past the tubes in the same direction as the refrigerant, so that the heat transfer fluid has the opportunity to absorb heat from the refrigerant passing through the tubes. The foregoing heat exchanger is generally applied to a so-called "reverse cycle" heat pump, in which a refrigerant is caused to flow through the tubes in a direction opposite to that of the heat transfer fluid, to absorb heat from the heat transfer fluid, and then to be circulated again so that the heat exchanger can perform its function. The heat transfer fluid is generally water or a water/glycol mixture, and in this context a heat exchanger may be said to be capable of heat transfer at a high level when the performance of the heat exchanger is considered in terms of how much of the heat transfer fluid is circulated through the exchanger. The reason that the heat transfer fluid is generally water or a water/glycol mixture is because these materials are suitable for the heat transfer fluid in this context, and it is known that the heat transfer fluid can be a liquid, such as water, but also it can be a gas, such as air, and a liquid can be a gas, so that the use of a heat transfer fluid can be chosen on a number of different bases. For example, the fluid may be chosen for a particular heat transfer context because of its suitability for particular circumstances, and for example, it may be desirable to obtain a heat transfer fluid having a relatively high boiling point and relatively high latent heat, or it may be desirable to obtain
